IVUS PCI Left Main | Radcliffe cardiology

Abstract. Intravascular ultrasound imaging (IVUS) was performed to elucidate the discrepancy between clinical history and angiographic findings and to measure the diameter and area of the lumen of the normal left coronary artery in 55 patients who presented with chest pain but

had normal coronary angiograms.

Coronary intravascular ultrasound: a closer view | Heart Intravascular ultrasound (IVUS) has emerged as an important adjunctive modality to angiography. IVUS offers precise imaging of the vessel size, plaque morphology and the presence of dissections and guides interventional procedures including stent sizing, assessing residual narrowing and stent apposition and expansion.

With the growing interest in vascular biology and understanding of the metabolically active atherosclerotic plaque, intravascular ultrasound (IVUS) imaging fills a gap in our understanding of coronary disease, as it allows in vivo examination of both the arterial wall and the lumen of the coronary arteries with high resolution.

IVUS PCI Left Main | Radcliffe cardiology

The principle of IVUS imaging is based on the ultrasound waves produced by the oscillatory movement of a transducer. 1 Commercially available IVUS systems have transducers mounted on catheters that are compatible with guiding catheters in sizes of 5Fr or larger. These catheters can be inserted into the coronary artery over a 0.014 inch conventional guide wire and imaging can be obtained by manual or motorised pullback.

Intravascular Ultrasound (or IVUS) allows us to see a coronary artery from the inside-out. This unique point-of-view picture, generated in real time, yields information that goes beyond what is possible with routine imaging methods, such as coronary angiography, performed in the cath lab, or even non-invasive Multislice CT scans.

Near-infrared spectroscopy (NIRS) intravascular ultrasound can be used to image mildly obstructive or nonobstructive coronary arteries with the aim of identifying both nonculprit arteries and patients at high risk for future cardiovascular events and should be considered for patients undergoing cardiac catheterization with possible percutaneous coronary intervention (PCI), according to study results published in The Lancet.
